Differential Topology And Quantum Field

The remarkable developments in differential topology and how these recent advances have been applied as a primary research tool in quantum field theory are presented here in a style reflecting the genuinely two-sided interaction between mathematical physics and applied mathematics.

Specifically, we will start with an $SU(N)$ theory and let its theta parameter vary in space. The two sides of the interface are (conjectured to be) confining, gapped, and invertible. But anomaly considerations show that the interface supports a nontrivial 3d topological quantum field theory (TQFT) and the full 4d theory does not confine there.

However, when it comes to Quantum Field Theory, I feel that very much revolves (especially from the math-community side) around topological and algebraic questions. There is for example a visible math-community with analysis background working on mathematical quantum mechanics, but I never noticed this community in Quantum Field Theory.

Geometry and topology at Berkeley center around the study of manifolds, with the incorporation of methods from algebra and analysis. The principal areas of research in geometry involve symplectic, Riemannian, and complex manifolds, with applications to and from combinatorics, classical and quantum physics, ordinary and partial differential equations, and representation theory.

This was group theory, which played an important role in both quantum field theory and differential geometry. This was, however, gradually supplemented by topology and functional analysis in the mathematical description of cosmological as well as quantum field theory phenomena.
