The design of instrumentation amplifier involves three Opamps with two of them used in non inverting amplifier configuration and the other in differential amplifier configuration. Also it involves seven resistors with 3 pairs of equal resistors R1, R2, R3 and R4. The circuit diagram of instrumentation amplifier is shown in below figure.

Analog Devices Instrumentation Amplifier Application Guide
An instrumentation amplifier is a type of differential amplifier that has been outfitted with input buffer amplifiers, which eliminate the need for input impedance matching and thus make the amplifier particularly suitable for use in measurement and test equipment. Additional characteristics include very low DC offset, low drift, low noise, very high open-loop gain, very high common-mode rejection ratio, and very high input impedances. Instrumentation amplifiers are used where great accuracy and

Instrumentation amplifiers have uses in nearly every field of electronics; they fulfill a specific role in circuits needing the advantages of high input impedance with good gain while providing common mode noise rejection and fully differential inputs. With such widespread use, this is a device every engineer should have in his tool belt.

Practical Uses of Instrumentation Amplifiers - LEKULE
An instrumentation amplifier is a purpose designed device, and unlike opamps there is no user accessible feedback terminal. The gain can be controlled by a single resistor, and the reference can be earth/ ground (as is normally the case), or some other voltage as required for your application.

The goal of this module is to provide an understanding of the indirect current feedback (ICF) architecture of instrumentation amplifiers and to give some applications insight to leverage its benefits in precision analog designs. The traditional three op-amp instrumentation amplifier architecture will be discussed and then compared to the indirect current feedback architecture.
